Theorem 1.1 of [1] states that for any k > 1 there exists a smooth simply connected closed 4k-dimensional manifold with finite π_2 and non-vanishing \hat{A} -genus which admits a smooth effective S^1 -action. The proof of this theorem was based on a general surgery lemma [1, Lemma 2.1]. As has been pointed out to us by Michael Wiemeler, the surgery lemma is not true in the form stated. Additional assumptions are necessary to ensure that the surgery can be done equivariantly. The purpose of this note is to remedy this situation and to give a proof of the theorem above using explicit equivariant surgeries. For k > 2 the proof is essentially the one given in [1], for k = 2 we apply [5, Thm. 1.3].

Theorem 1.1 For any k > 1 there exists a smooth simply connected 4k-dimensional π_2 -finite manifold M' with smooth effective S^1 -action and $\hat{A}(M') \neq 0$.

Proof: As in [1] we consider $M := \mathbb{C}P^{2k}$ with a linear S^1 -action. More precisely, we consider the S^1 -action on M induced by the linear action

$$S^{1} \times \mathbb{C}^{2k+1} \to \mathbb{C}^{2k+1}$$
$$(\lambda, (z_{0}, \dots, z_{2k-2}, z_{2k-1}, z_{2k})) \mapsto (z_{0}, \dots, z_{2k-2}, \lambda \cdot z_{2k-1}, \lambda^{-1} \cdot z_{2k}).$$

The connected components of the fixed point set M^{S^1} are two isolated fixed points and $N := \mathbb{C}P^{2k-2}$.

We first assume that the dimension of N is > 4, i.e., that k > 2. Let $\kappa: M \to BSO$ be a classifying map for the stable normal bundle of M. Consider a map $f: S^2 \to N$ such that its composition with the inclusion map $N \hookrightarrow M$ represents a generator of the kernel of $\kappa_*: \pi_2(M) \to \pi_2(BSO)$. Since dim N > 4 we may assume that f is a smooth embedding.

By construction, the normal bundle of $f(S^2) \subset M$, viewed as a real non-equivariant vector bundle, is trivial. It splits equivariantly as a direct sum $E \oplus F$, where E is the normal bundle of $f(S^2)$ in N and F is the restriction to $f(S^2)$ of the normal bundle ν_N of N in M. We note that ν_N can be identified

with the direct sum $\overline{\gamma} \oplus \overline{\gamma}$, where γ denotes the canonical complex line bundle over $N = \mathbb{C}P^{2k-2}$. Under this identification, $\lambda \in S^1$ acts on one summand by multiplication with λ and on the other summand by multiplication with λ^{-1} . By changing the complex structure, we can identify ν_N equivariantly with the complex vector bundle $\gamma \oplus \overline{\gamma}$, where $\lambda \in S^1$ now acts by complex multiplication on both summands. In particular, F can be identified equivariantly with the complex vector bundle $(\gamma \oplus \overline{\gamma})|_{f(S^2)}$ which is trivial. Also, E is a trivial real vector bundle over $f(S^2)$, since E is stably trivial and has rank rk $E = \dim N - 2 = 4k - 6 > 2$. Moreover, S^1 acts trivially on E. Hence, F (resp. E) can be extended as a complex (resp. real) vector bundle over the disk D^3 .

In conclusion, the normal bundle of $f(S^2) \subset M$ splits equivariantly as the direct sum of a trivial vector bundle E with trivial S^1 -action and a trivial vector bundle F with non-trivial S^1 -action, and the direct sum extends equivariantly to the disk D^3 , where S^1 acts trivially on D^3 . In particular, the sphere normal bundle of $f(S^2) \subset M$ can be extended equivariantly to the disk. Hence, one can perform S^1 -equivariant surgery on $f(S^2)$. The result of the surgery is a simply connected S^1 -manifold M' with $\pi_2(M') \cong \mathbb{Z}/2\mathbb{Z}$ which is S^1 -equivariantly bordant to M.

It is well-known that the \hat{A} -genus does not vanish on $\mathbb{C}P^{2k}$. Since M' is bordant to $\mathbb{C}P^{2k}$ the same is true for M'. This completes the argument if k > 2.

For k=2, one cannot argue as above, since the bundle E does not extend to the disk. In fact, if $S^2 \subset N = \mathbb{C}P^2$ represents a non-trivial element of $\pi_2(M)$ then the Euler class of its normal bundle in N is non-zero.

To construct M' for k=2 we will apply a different construction which involves non-equivariant surgery in the orbit space. This construction, which was pointed out to us by Michael Wiemeler, is quite general, the argument below is a special case of [5, Thm. 1.3].

Let us consider $M = \mathbb{C}P^4$ with the S^1 -action as before. Let M_0 denote the union of principal orbits and $i: M_0 \hookrightarrow M$ the inclusion map. Note that the complement of M_0 is the union of N and a 2-sphere which contains the two isolated fixed points. The restriction of the action to M_0 defines a principal S^1 -bundle $p: M_0 \to B_0$ with base space $B_0 := M_0/S^1$. Note that $i_*: \pi_2(M_0) \to \pi_2(M)$ is an isomorphisms and $p_*: \pi_2(M_0) \to \pi_2(B_0)$ is injective.

Consider a map $f: S^2 \to M_0$ such that $i \circ f$ represents a generator of the kernel of $\kappa_*: \pi_2(M) \to \pi_2(BSO)$. Up to homotopy we may assume that f and $\overline{f}:=p\circ f: S^2 \to B_0$ are smooth embeddings. It follows that the restriction of the principal S^1 -bundle to $\overline{f}(S^2)$ is trivial (with a section given by f) and that the normal bundle of $\overline{f}(S^2) \subset B_0$ is trivial. Hence, the disk normal bundle of $\overline{f}(S^2)$ can be identified with $\overline{f}(S^2) \times D^5$ and the disk normal bundle of $S^1 \cdot f(S^2) = p^{-1}(\overline{f}(S^2)) \cong S^1 \times f(S^2)$ can be identified equivariantly with $S^1 \times f(S^2) \times D^5$, where S^1 acts on S^1 by left multiplication and acts trivially on the other factors. Next perform surgery for $\overline{f}(S^2) \times D^5 \subset B_0$ and make the corresponding modification for $S^1 \times f(S^2) \times D^5 \subset M_0$, i.e., consider

$$(M_0 - (S^1 \times f(S^2) \times \overset{\circ}{D^5})) \cup (S^1 \times D^3 \times S^4).$$

Let us denote the results of these modifications by B'_0 and M'_0 , respectively, and let

$$M' := M'_0 \cup (M - M_0).$$

As before, the inclusion $M'_0 \hookrightarrow M'$ induces an isomorphism on π_2 and the projection in the principal S^1 -bundle $M'_0 \to B'_0$ is injective on π_2 . It follows that $\pi_2(M') \cong \mathbb{Z}/2\mathbb{Z}$. In addition, the long exact sequence of homotopy groups for the principal S^1 -bundles together with the Seifert-van Kampen theorem shows that M' is simply connected. By construction, M' is equivariantly bordant to $M = \mathbb{C}P^4$. Hence, $\hat{A}(M') = \hat{A}(\mathbb{C}P^4) \neq 0$. This completes the argument for k = 2.

- Remarks 1.2 1. LeBrun and Salamon conjectured that any positive quaternionic Kähler manifold is symmetric. The conjecture has been proved by Hitchin, Poon-Salamon and LeBrun-Salamon in dimensions ≤ 8 . Haydeé and Rafael Herrera [3] offered a proof in dimension 12 involving a vanishing statement for the Â-genus of π_2 -finite manifolds with S^1 -action. The purpose of [1, Thm. 1.1] was to show that this statement cannot be correct.
 - 2. Recently, Buczyński, Wiśniewski and Weber [2] gave a proof of the LeBrun-Salamon conjecture in dimensions 12 and 16 by showing that the corresponding twistor spaces are adjoint varieties.
 - 3. In [5] Wiemeler uses equivariant surgery to construct examples of manifolds, as in Thm. 1.1, which have non-trivial fundamental group. The examples have non-spin universal covering. On the other hand, Wiemeler shows that the elliptic genus is rigid for any closed even-dimensional S¹-manifold whose universal covering is spin. Using an argument of Hirzebruch and Slodowy [4] he concludes that the Â-genus of such a manifold vanishes if the action is non-trivial.

We like to thank Michael Wiemeler for discussions and valuable comments.
